# RNA INTERFERENCE PATHWAY GENES AS TOOLS FOR TARGETED GENETIC INTERFERENCE

# Related Application Information

This application claims priority from provisional application serial numbers 60/159,776, filed October 15, 1999, and 60/193,218, filed March 30, 2000.

# Statement as to Federally Sponsored Research

Funding for the work described herein was provided by the federal government (GM58800 and GM37706), which has certain rights in the invention.

# Field of the Invention

This invention relates to the discovery of genes whose expression products are involved in mediation of genetic interference.

#### Background of the Invention

All eukaryotic organisma share similar mechanismas for information transfer from DNA to RNA to protein. RNA interfreence represents an efficient mechanism for inactivating this transfer process for a specific targeted gene. Targeting is mediated by the sequence of the RNA molecule introduced to the cell. Double-stranded (ds) RNA can induce sequence-specific inhibition of gene function (genetic interference) in several organisms including the nematode, C. elegour (Fire, et al., 1998, Nature 391:306-811), plants, trypanosomes, Pronophila, and planaria (Waterhouse et al., 1998, Proc. Natl. Acad. Sci. USA 95:1468-7, Roye et al., 1998, Proc. Natl. Local Sci. USA 95:14687-14692; Kennerdell and Carthew, 1998, Cell 95:1017-1026; Misquitta and Patterson, 1999, Proc. Natl. Acad. Sci. USA 96:49-505-91. The discovery that dRNA can induce genetic interference in organisms from several distinct phyla suggests a conserved of mechanism and perhaps a conserved physiological role for the interference process. Althous herealt modes of RNA have been proposed (Bulanome), 1999, Curr. Biol.

1

9:R599-R601; Sharp, 1999, Genes & Dev. 13:139-141) the mechanisms of action of specific components of the pathway are not known.

Attempts to overexpress a gene (e.g., a transgene) office lead only to transient expression of the gene. Furthermore, the common understable effect of 5 "cosuppression" can occur in which a corresponding endogenous copy of the transgene becomes inactivated. In some cases, transgene silencing leads to problems with the commercial or therapeutic application of transgenic technology to alter the genetic makeup of a cell, organizm, or human quisfert.

#### Summary of the Invention

10

The present invention relates to the discovery of RNA interference (RNAi) pathway genes which are involved in mediating double-stranded RNA-dependent gene allencing (genetic interference). RNAi requires a set of conserved cellular factors to 19 press gene expression. These factors are the components of the RNAi pathway. The RNAi pathway mutations and genes described herein (e.g., rde-1, rde-2, rde-3, rde-4, rde-5, mut-2, and mut-7), and their protein products (e.g., RDE-1 and RDE-4) are useful tools for investigating the mechanisms involved in RNAi and developing methods of modulating the RNAi pathway. The expanses and methods described herein are useful for modulating the RNAi pathway and may be used in conjunction with other methods to involving the use of genetic inhibition by distNA (e.g., see U.S.N. 09/15,257, filed Docember 13, 1996, incorporated herein by reflerence in its entirety).

RNAi pathway components (e.g., RDE-I, RDE-I) provide activities necessary for interference. These activities may be absent or not sufficiently activated in many cell types, including those of organisms such as humans is which genetic interference may have potential thempeutic value. Components of the RNAi puthway in C. elegans may be sufficient when provided through transgenesis or as direct RNA: protein complexes to activate or directly mediate genetic interference in heterologous cells that are deficient in RNAi.

Nucleic acid sequences encoding RNAi pathway components (e.g., RDE-1, RDE-30 4) are useful, e.g., for studying the regulation of the RNAi pathway. Such sequences can also be used to generate knockout strains of animals such as C. elevans.

The nucleic acids of the invention include nucleic acids that hybridize, e.g., under stringent hybridization conditions (as defined berein), to all or a portion of the nucleotide sequence of SEQ ID NO: (Figure 6A-C) or its complements, SEQ ID NO: (Figure 6A-C) or its complement, or SEQ ID NO: (Figure 6A-C) or its complement, or SEQ ID NO: (Figure 6A-C) or its complement. The hybridizing portion of the hybridizing portion of the hybridizing portion of the hybridizing portion of the hybridizing nucleic acids are preferably 9.30, 50, 50, or 70 bases long. Preferably, the hybridizing portion of the hybridizing nucleic acid is 80%, more preferably 95%, or even 98% or 100% identical to the sequence of a portion or all of a nucleic acid encoding an RDE-1 polyreptide. Hybridizing nucleic acid of the type described above can be used as a cloning probe, a primer (e.g., a PCR primer), or a diagnostic probe. Preferred hybridizing nucleic acids encode a polyreptide having some or all of the biological activities possessed by a naturally-occurring RDE-1 polyreptide or all of the biological activities possessed by a naturally-occurring RDE-1 polyreptide or all of the biological activities possessed by a naturally-occurring RDE-1 polyreptide or all of the biological activities possessed by a naturally-occurring RDE-1 polyreptide or all of the bloogical activities of the second or all of the bloogical activities of the second or all of the bloogical activities of the second or all of the bloogical activities of the second or all of the bloogical activities of the second or all of the bloogical activities of the second or all of the bloogical activities of the second or all of the bloogical activities of the second or all of the bloogical activities of the second or all of the second or all of the second or all of the bloogical activities of the second or all of t

Hybridizing mucleic acids may encode a protein that is aborter or longer than the RDE-1 protein or RDE-4 protein described herein. Hybridizing nucleic acids may also encode proteins that are related to RDE-1 or RDE-4 (e.g., proteins encoded by genes that include a portion having a relatively high degree of identity to the rde-1 gene or rde-4

reter (C)

an RDE-4 polypentide e.g., as determined in the assays described below.

gene described herein).

The invention also features purified or isolated RDE-1 polypeptides and RDE-4 polypeptides. RDE-1 and RDE-4 polypeptides are useful for generating and testing antibodies that specifically bind to an RDE-1 or an RDE-4. Such autibodies can be used, e.g., for studying the RNA1 pathway in C. elegans and other organisms. As used herein, both "protein" and "polypeptide" means any chain of antino exide, regardless of length or post-translational modification (e.g., glyconylstion or phosphorylation). Thus, the term "RNA1 pathway polypeptide" includes a fall-length, naturally occurring RNA1 pathway polypeptide includes a fall-length, naturally occurring RNA1 pathway polypeptides that correspond to a fall-length, naturally occurring RNA1 pathway polypeptides that correspond to a fall-length, naturally occurring RNA1 pathway protein or RDE-4 protein, a well as recombinantly or synthetically produced polypeptides that correspond to a fall-length, naturally occurring RNA1 pathway protein.

RNAi pathway mutations and strains harboring those mutations (e.g., rde-1, rde-2, 30 rde-3, rde-4, rde-5) are useful for studying the RNAi pathway, including identification of modulators of the RNAi pathway.

RNAi pathway components (e.g., those associated with mut-7 and rde-2) can be used to desilence or prevent silencing of transgenes. To facilitate this function, such RNAi pathway components are inhibited using specific inhibitors of an RNAi pathway gene or its product.

In one embodiment, the invention includes an isolated nucleic acid molecule comprising a nucleotide sequence encoding an RDE-1 polypeptide. The nucleic acid molecule hybridizes under high stringency conditions to the nucleic acid sequence of Genbank Accession No. AF180730 (SEQ ID NO:2) or its complement, or the sequence of SEO ID NO:1 or its complement. In one embodiment, the isolated nucleic acid can 10 complement an rde-1 mutation. The invention also encompasses an isolated nucleic acid whose nucleotide sequence encodes the amino acid sequence of SEQ ID NO:3.

The invention also encompasses a substantially pure RDE-1 polypeptide encoded by the isolated nucleic acids described herein.

The invention features an antibody that specifically binds to an RDE-1 15 polypeptide.

5

The invention also includes a method of enhancing the expression of a transgene in a cell, the method comprising decreasing activity of the RNAi pathway. In one embodiment of this invention, rde-2 expression or activity is decreased.

The invention also features an isolated nucleic acid molecule comprising a 20 nucleotide sequence encoding an RDE-4 polypeptide, wherein the nucleic acid molecule hybridizes under high stringency conditions to the nucleic acid sequence of SEO ID NO:4 or its complement. The invention also encompasses an isolated nucleic acid encoding an RDE-4 polypeptide, wherein the nucleic acid can complement an rde-4 mutation. The invention also encompasses an isolated nucleic acid encoding an RDE-4 25 polypeptide, in which the nucleotide sequence encodes the amino acid sequence of SEO ID NO:5

The invention also features a substantially pure RDE-4 polypeptide encoded by the isolated nucleic acids described herein.

In another embodiment the invention features an antibody that specifically binds to an RDE-4 polypentide.

The invention also features a method of preparing an RNAi agent, the method

includes incubating a dsRNA in the presence of an RDE-1 protein and an RDE-4 protein.

The invention also features a method of inhibiting the activity of a gene by introducing an RNAi agent into a cell, such that the dsRNA component of the RNAi agent is targeted to the gene. In another embodiment of the invention, the cell contains 5 an exogenous RNAi pathway sequence. The exogenous RNAi pathway sequence can be an RDE-1 polypeptide or an RDE-4 polypeptide. In still another embodiment, a dsRNA is introduced into a cell containing an exogenous RNAi pathway sequence such as nucleic acid sequence expressing an RDE-1 or RDE-4,

An RNAi pathway component is a protein or nucleic acid that is involved in promoting dsRNA-mediated genetic interference. A nucleic acid component can be an RNA or DNA molecule. A mutation in a sene encoding an RNAi pathway component may decrease or increase RNAi pathway activity.

An RNAi pathway protein is a protein that is involved in promoting dsRNA mediated genetic interference.

15

25

30

A "substantially pure DNA" is a DNA that is not immediately contiguous with (i.e., covalently linked to) both of the coding sequences with which it is immediately contiguous (i.e., one at the 5' end and one at the 3' end) in the naturally-occurring genome of the organism from which the DNA of the invention is derived. The term therefore includes, for example, a recombinant DNA which is incorporated into a vector, into an 20 autonomously replicating plasmid or virus, or into the genomic DNA of a prokaryote or eukaryote; or which exists as a separate molecule (e.g., a cDNA or a genomic or cDNA fragment produced by PCR (polymerase chain reaction) or restriction endonuclease digestion) independent of other sequences. It also includes a recombinant DNA which is part of a hybrid gene encoding additional polypentide sequences.

By "inhibited RNAi pathway" is meant decreased inhibitory activity of a dsRNA which results in at least two-fold less inhibition by a dsRNA relative to its ability to cause inhibition in a wild type cell. Techniques for measuring RNAi pathway activity are described herein. The pathway can be inhibited by inhibiting a component of the pathway (e.g., RDE-1) or mutating the component so that its function is reduced.

A "substantially pure polypeptide" is a polypeptide, e.g., an RNAi pathway polypeptide or fragment thereof, that is at least 60%, by weight, free from the proteins

and naturally-occurring organic molecules with which it is naturally associated. Preferably, the preparation is at least 75%, more preferably at least 90%, and most preferably, the seasy 9%, by weight, RNA1 pathway polypeptide or fragment. A substantially pure RNA1 pathway polypeptide or fragment thereof is obtained, for 5 example, by extraction from a natural source; by expression of a recombinant nuclei ead de neoding an RNA1 pathway polypeptide or fragment theroof; or be chemically synthesizing the polypeptide or fragment. Purity can be measured by any appropriate method, e.g., column chromatography, polypecytamide get electrophoresis, or HPLC analysis.

10 By "specifically binds" is meant a molecule that binds to a particular entity, e.g., an RNAi pathway polypeptide, but which does not substantially recognize or bind to other molecules in a sample, e.g., a biological sample, which includes the particular entity, e.g. RDE-1.

AR RNAi agent is a deRNA molecule that has been treated with those components

of the RNAi pathway that are required to confer RNAi activity on the deRNA. For
example, treatment of a deRNA under conditions that include RDE-1 and RDE-4 results
in an RNAI agent. Injection of such an agent into an animal that is mutent for RDE-1 and
RDE-4 will result in activation of the RNAi pathway with respect to a targeted gene.
Typically, the daRNA used to trigger the formation of the RNAi agent is selected to be an

RNA corresponding to all or a portion of the methodic possumence of the tested erem.

Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Although methods and materials similar or equivalent to those described herein can be used in the practice or testing of the present invention, suitable methods and materials are described below. All publications, patent applications, patents, and other references mentioned herein are incorporated by reference. In addition, the materials, methods, and examples are illustrative only and not intended to be limiting.

Other features and advantages of the invention will be apparent from the detailed description, and from the claims.

#### Brief Description of the Drawings

Figure 1A illustrates the genetic scheme used to identify rde mutants.

Figure 1B is an illustration summarizing data from the genetic mapping of rde and mut mutations. The vertical bars represent chromosomes; LGI, LGIII, and LGV.

5 Reference genetic markers are indicated at the right of each chromosome and the relative genetic positions of the rde and mut alleles are indicated at the left.

Figure 2A is a graphical representation of experiments investigating the sensitivity of rule and must strains to RNA1 by microinjection. The RNA species indicated above each graph was injected at high concentration (pos-1: 7mg/ml, por-2: 5mg/ml, sqr-10 3: 7mg/ml). The strains receiving injection are indicated at the left and the horizontal bar graphs reflect the percent of progeny that exhibited genetic interference. The Unc marker mustants used are also indicated. The percent embryonic lethality of F1 progeny is plotted as standed buss and the fraction of affected recovery is indicated at the right of each error.

Figure 2B is a graphical representation of experiments demonstrating that animals bonorogyous for rule and nutralleles are resistant to RNAI tageting maternally expressed genes, por-1 and por-2. The percent emboyonic lebality of FI prospeny is plotted as shaded bars and the fraction of affected prospeny is indicated at the right of each graph, Figure 3 is a schematic representation of bonocytous rule-level299 and rule-

25

#### Detailed Description

Mutations have been discovered that identify genes involved in dsRNA-mediated genetic interference (RNA). RNAi pathway genes encode products involved in genetic interference and eru useful for mediating or enhancing genetic interference. These genes is encode mediators of double-stranded RNA-mediated interference. The mediators can be nucleic acid or protein. RNAi pathway genes are also useful for mediating specific processes, e.g., a gene that mediates dsRNA uptake by cells may be useful for transporting other RNAs into cells or for finitistating entry of agents such as drugs into cells. The methods and examples described below illustrate the identification of RNAi pathway components, the uses of RNAi pathway components, mutants, genes and their procluses.

# Identification of an RNAi-deficient mutants and an RNAi pathway gene, rde-1

RNAi pathway genes were identified using screens for C. elegons strains mutant for RNAi (Examples 2 and 3). The mutations were further characterized for germline and somatic effects, effects on transposon mobilization, X chromosome loss and transgene silencing, and target tissue activity (Examples 4 and 5).

The rde-1 gene was identified using YACs (yeast artificial chromosomes) and 30 cosmids to rescue rde-1 mutants. Based on the identified sequence, a cDNA sequence WO 01/29058 PCT/II500/28470

was identified in a C. elegans cDNA library and the complete cDNA sequence determined (Example 6).

20

30 mismatch

#### Identification of RNAi Pathway Genes Homologous to rde-1, rde-2, rde-3, and rde-4

RNAi pathway genes from C. elegans (such as those described herein) and from other organisms (e.g. plant, mammalian, especially human) are useful for the elucidation of the blochemical pathways involved in genetic interference and for developing the uses of RNAi pathway genes described herein.

Several approaches can be used to isolate RNAi pathway genes including twohylicid screens, complementation of C. elegam mutants by expression libraries of cloned
heterologous (e.g.-, plant, mammalian, human) cDNAs, polymenase chain reactions (PCR)
primed with degenerate oligonucleotides, low stringency hybridization screens of
heterologous cDNA or genomic libraries with a C. elegam RNAi pathway gene, and
database screens for sequences homologous to an RNAI pathway gene. Hybridization is
performed under stringent conditions. Alternatively, a labeled fragment can be used to
serven a genomic library derived from the organism of interest, again, using appropriately
stringent conditions. Such stringent conditions are well known, and will vary predictably
depending on the specific organisms from which the library and the labeled sequences are
elevitors.

 $T_{\rm m}$ , which is the temperature at which a probe dissociates from a target DNA. This melting temperature is used to define the required stringency conditions. If sequences are to be identified that are related and abstantially identified to the probe, rather than identical, then it is useful to first establish the lowest temperature at which only bomologous bybridization occurs with a particular SSC or SSPE concentration. Then assume that 18 minantaching results in 1°C decrease in the  $T_{\rm m}$  and reduce the temperature of the final weah accordingly (for example, if sequences with  $\geq$  95% identity with the probe are sought, decrease the final weah temperature by 5°C). Note that this assumption is very approximate, and the extend thange in  $T_{\rm m}$  on the between 0.5° and 1.5° Cent 1%

Nucleic acid duplex or hybrid stability is expressed as the melting temperature or

As used herein, high stringency conditions include hybridizing at 68°C in 5x SSC/5x Denhardt solution/1.0% SDS, or in 0.5 M NaiIPO<sub>4</sub> (pH 7.2)1 mM EDTA7% SDS, or in 50% formamide 0.25 M NaIPO<sub>4</sub> (pH 7.2)0.25 M NaC/U mM EDTA7% SDS, and washing in 0.2x SSC/0.1% SDS at room temperature or at 42°C, or in 0.1x SSC/0.1% SDS at 68°C, or in 40 mM NaIPO<sub>4</sub> (pH 7.2)1 mM EDTA4/98 SDS at 50°C, or in 40 mM NaIPO<sub>4</sub> (pH 7.2)1 mM EDTA4/98 SDS at 50°C, or in 40 mM NaIPO<sub>4</sub> (pH 7.2)1 mM EDTA4/98 SDS at 50°C. Moderately stringent conditions include washing in 3x SSC at 42°C. The parameters of salt concentration and temperature can be varied to achieve the desired level of identity between the probe and the traget motelled acid.

For guidance regarding such conditions see, for example, Sambrook et al., 1989, Molecular Cloning, A Laboratory Manual, Cold Springs Harbor Press, N.Y.; and Ausubel et al. (eds.), 1995, Current Protocols in Molecular Biology, (John Willey & Sons, N.Y.) at Unit 2.10.

10

15

20

Methods of screening for and identifying homologs of C. elegour RNAi genes (e.g., rde-1) are known in the art. For example, complementation of mutants, described in the Examples can be performed using nucleic acid sequences from organisms other than C. elegour. Methods of inhibiting expression of a target gene in a cell using daRNA are known in the art and are exemplified in U.S.S.N. 09/215,237, Biod Docember 18, 1998, which is incorporated herein by reference in its entirety.

Another method of screening is to use an identified RNAi pathway gene sequence to screen a cDNA or genomic library using low stringency hybridizations. Such methods are known in the art.

PCR with degenerate oligonucleotides is another method of identifying homologs of RNAi pathway genes (e.g., human rde-1). Homologs of an RNAi pathway gene (identified in other species are compared to identified professor programs with a high degree of homology (as in the sequence comparison shown in Figure 4). These regions of high homology are selected for designing PCR primers that maximize possible base-painting with heterologous genes. Construction of such primers involves the use of oligonucleotide mixtures that account for degeneracy in the genetic code, i.e., allow for the possible base changes in an RNAi pathway gene that does not affect the amino acid sequence of the RNAi pathway protein. Such primers may be used to amplify and close

possible RNAi pathway gene fragments from DNA isolated from another organizan (e.g., mouse or human). The latter are sequenced and those encoding protein fragments with high degrees of homology to fragments of the RNAi pathway protein are used as mucicie acid probes in subsequent screens of genomic DNA and cDNA libraries (e.g., mouse or burnan). Full-length genes and cDNAs having substantial homology to the previously identified RNAi pathway gene are identified in these screens.

To produce an RNAi pathway gene product (e.g., RDR-1) a sequence encoding the gene is placed in an expression vector and the gene expressed in an appropriate cell type. The gene product is isolated from such cell lines using methods known to those in the art, and used in the assays and procedures described herein. The gene product can be a complete RNAi enthway restoris (e.g. RDE-1) or a famement of such a rowein.

#### Methods of Expressing RNAi Pathway Proteins

15

25

Full-length polyspetides and polyspetides corresponding to one or more domains of full-length RNA1 pathway protein, e.g., the RNA-binding domain of RDE-4, are also within the scope of the invention. Also within the invention are fusion proteins in which a portion (e.g., one or more domains) of an RDE-1 or RDE-4) is fused to an unrelated protein or polyspetide (i.e., a fusion partner) to create a fusion protein. The fusion partner can be a moiety selected to facilitate purification, detection, or solubilization, or to provide some other function. Fusion proteins are generally produced by expressing a hybrid gene in which a muchotide sequence encoding all or a portion of of an RNA1 pathway protein joined in-finame to an unclosdies progress encoding the fusion partners. Fusion partners include, but are not limited to, the constant region of an immunoglobulin (IgF-C). A fusion protein in which an RNA1 pathway protein is fused to IgF-C can be more stable and have a loner land life in the body that he nolventifice on its fused to IgF-C can be more stable and have a loner land life in the body that he nolventifice on its description.

In general, RNAI pathway proteins (e.g., RDE-1, RDE-1) according to the invention can be produced by transformation (transfection, transaction, or infection) of a host cell with all or part of an RNAI pathway protein-encoding DNA fragment (e.g., one of the cDNAs described herein) in a suitable expression vehicle. Suitable expression vehicle include: plasmids, wiral particles, and phage. For insect cells, beactiowirus extression vehicles are active to the control of t

integrated into the host cell genome. In some circumstances, it is desirable to employ an inducible expression vector, e.g., the LACSWITCH™ Inducible Expression System (Stratagene; LaJolla, CA).

Those skilled in the field of molecular biology will understand that any of a wide 5 variety of expression systems can be used to provide the recombinant protein. The precise host cell used is not critical to the invention. The RNAi pathway protein can be produced in a prokaryotic host (e.g., E. coli or B. subtilis) or in a eukaryotic host (e.g., Saccharomyces or Pichia; mammalian cells, e.g., COS, NIH 3T3 CHO, BHK, 293, or Hell a cells: or insect cells).

10

20

Proteins and polypeptides can also be produced in plant cells. For plant cells viral expression vectors (e.g., cauliflower mosaic virus and tobacco mosaic virus) and plasmid expression vectors (e.g., Ti plasmid) are suitable. Such cells are available from a wide range of sources (e.g., the American Type Culture Collection, Rockland, MD: also, see. e.g., Ausubel et al., Current Protocols in Molecular Biology, John Wiley & Sons, New 15 York, 1994). The methods of transformation or transfection and the choice of expression vehicle will depend on the host system selected. Transformation and transfection methods are described, e.g., in Ausubel et al., supra: expression vehicles may be chosen from those provided, e.g., in Cloning Vectors: A Laboratory Manual (P.H. Pouwels et al., 1985, Supp. 1987).

The host cells harboring the expression vehicle can be cultured in conventional nutrient media adapted as need for activation of a chosen gene, repression of a chosen gene, selection of transformants, or amplification of a chosen gene.

One preferred expression system is the mouse 3T3 fibroblast host cell transfected with a pMAMneo expression vector (Clontech, Palo Alto, CA), pMAMneo provides an RSV-LTR enhancer linked to a dexamethasone-inducible MMTV-LTR promotor, an SV40 origin of replication which allows replication in mammalian systems, a selectable neomycin gene, and SV40 splicing and polyadenylation sites. DNA encoding an RNAi pathway protein would be inserted into the pMAMneo vector in an orientation designed to allow expression. The recombinant RNAi pathway protein would be isolated as 30 described herein. Other preferable host cells that can be used in conjunction with the

pMAMneo expression vehicle include COS cells and CHO cells (ATCC Accession Nos. CRL 1650 and CCL 61, respectively).

RNAi pathway polypeptides can be produced as fusion proteins. For example, the expression vector pUR278 (Ruther et al., EMBO. J. 21791, 1983), can be used to create 5 lacZ fusion proteins. The pGEX vectors can be used to express foreign polypeptides as fusion proteins with glustations 6-transferase (GST). In general, such flation proteins are soluble and on the easily purified from lysed cells by adsorption to glustations—gamone beads followed by elution in the presence of free glustatione. The pGEX vectors are designed to include thrombin or factor Xs protease cleavage sites so that the cloned target 0 gene product can be released from the GST moietr.

In an insect cell expression system, <u>Autographa cellifornica</u> nuclear polyhidrosis virus (AcNPV), which grows in <u>Snodoptara funiporda</u> cells, is used as a vector to express foreign genes. An RNA plathway protein coding sequence can be cloned individually into non-essential regions (for example the polyhedrin genn) of the virus and placed under control of an AcNPV prometer, e.g., the polyhedrin promoter. Successful insertion of a gene encoding an RNAI pathway polypeptide or protein will result in insertion of a gene encoding an RNAI pathway polypeptide or protein will result in insertion of a gene encoding an RNAI pathway polypeptide or protein will result in insertivation of the polyhedrin gene and production of non-occluded recombinant virus (i.e., virus lacking the proteinanceus cost encoded by the polyhedrin gene). These recombinant viruses are then used to infect speciopters freeigned; cells in which the inserted gene is expressed (age, e.g., Smith et al., J. Firol. 46:584, 1983; Smith, U.S. Patent No. 4.21.5.551).

In mammalian host cells, a number of viral-based expression systems can be utilized. When an adenovirus is used as an expression vector, the RNAI pathway protein mucleic acid sequence can be ligated to an adenovirus transcription's translation control complex, e.g., the late promoter and tripartite leader sequence. This chimeric gene can then be inserted into the adenovirus genome by in witro or in wive recombination. Insertion into a non-essential region of the viral genome (e.g., region EI or E3) will result in a recombinant virus that is viable and capable of expressing an RNAI pathway gene product in infected hosts (ggs. e.g., Logun, Proc. Natl. Acad. Sci. USA 81:3655, 1984).

Specific initiation signals may be required for efficient translation of inserted nucleic acid sequences. These signals include the ATG initiation codon and adjacent

30

sequences. In cases where an entire native RNAi pathway protein gene or cDNA. including its own initiation codon and adjacent sequences, is inserted into the appropriate expression vector, no additional translational control signals may be needed. In other cases, exogenous translational control signals, including, perhaps, the ATG initiation 5 codon, must be provided. Furthermore, the initiation codon must be in phase with the reading frame of the desired coding sequence to ensure translation of the entire insert. These exogenous translational control signals and initiation codons can be of a variety of origins, both natural and synthetic. The efficiency of expression may be enhanced by the inclusion of appropriate transcription enhancer elements, transcription terminators (Bittner et al., Methods in Enzymol, 153:516, 1987).

RNA i pathway polypeptides can be expressed directly or as a fusion with a heterologous polypeptide, such as a signal sequence or other polypeptide having a specific cleavage site at the N-and/or C-terminus of the mature protein or polypeptide. Included within the scope of this invention are RNAi pathway polypeptides with a heterologous signal sequence. The heterologous signal sequence selected should be one that is recognized and processed, i.e., cleaved by a signal peptidase, by the host cell. For prokaryotic host cells a prokaryotic signal sequence is selected, for example, from the group of the alkaline phosphatase, penicillinase, lpp, or heat-stable enterotoxin II leaders. For yeast secretion a yeast invertase, alpha factor, or acid phosphatase leaders may be selected. In mammalian cells, it is generally desirable to select a mammalian signal sequences.

10

25

30

A host cell may be chosen which modulates the expression of the inserted sequences, or modifies and processes the gene product in a specific, desired fashion. Such modifications (e.g., glycosylation) and processing (e.g., cleavage) of protein products may be important for the function of the protein. Different host cells have characteristic and specific mechanisms for the post-translational processing and modification of proteins and gene products. Appropriate cell lines or host systems can be chosen to ensure the correct modification and processing of the foreign protein expressed. To this end, eukaryotic host cells that possess the cellular machinery for proper processing of the primary transcript, glycosylation, and phosphorylation of the gene product can be used. Such mammalian host cells include, but are not limited to, CHO.

VERO, BHK, HeLa, COS, MDCK, 293, 3T3, WI38, and in particular, choroid plexus cell lines

Alternatively, an RNAi pathway protein can be produced by a stably-transfreted mammalian cell line. A number of vectors suitable for stable transfection of mammalian of line. A number of vectors suitable for stable transfection of mammalian of line are at least the stable transfection of mammalian of lines are also publicly available, e.g., in Ausubel et al. (1932m.). In one example, cDNA encoding an RNAi pathway protein (e.g., RDF-1 or RDE-4) is closed into an expression vector that includes the dihydrofolate reductase (DHFR) gene. Integration of the plasmid and, therefore, the RNAi pathway protein-encoding gene into the host cell to chromosome is selected for by including 0.01-300 pM methotrexate in the cell culture medium (as described in Ausubel et al., 1932m.). This dominant selection can be accommissible in most cell toward.

Recombinant protein expression can be increased by DHFR-mediated memorial m

was:

A number of other selection systems can be used, including but not limited to the berpes simplex virus thymidine kinase, lapvosunthine-guantine phosphorihosyl-transferase, and adenine phosphoribosyl-transferase, and adenine phosphoribosyl-transferase, and selection of the state of the selection of the selection

Alternatively, any fusion protein can be readily purified by utilizing an antibody specific for the fusion protein being expressed. For example, a system described in

30

Janknecht et al., Proc. Natl. Acad. Sci. USA, 88:8972 (1981), allows for the ready purification of non-denatured fusion proteins expressed in human cell lines. In this system, the gene of interest is subcloned into a vaccinia recombination plasmid such that the gene's open reading frame is translationally fused to an amino-terminal tag consisting 5 of six histidine residues. Extracts from cells infected with recombinant vaccinia virus are loaded onto Ni2+ nitriloacetic acid-agarose columns, and histidine-tagged proteins are selectively eluted with imidazole-containing buffers.

Alternatively, an RNAi pathway protein or a portion thereof, can be fused to an immunoglobulin Fc domain. Such a fusion protein can be readily purified using a protein 10 A column.

#### Antibodies that Recognize RNAi Pathway Proteins

25

Techniques for generating both monoclonal and polyclonal antibodies specific for a particular protein are well known. The invention also includes humanized or chimeric antibodies, single chain antibodies, Fab fragments, F(ab')2 fragments, and molecules produced using a Fab expression library.

sament:

Antibodies can be raised against a short peptide epitope of an RNAi pathway gene (e.g., rde-1), an epitope linked to a known immunogen to enhance immunogenicity, a long fragment of an RNAi pathway gene, or the intact protein. Such antibodies are useful 20 for e.g., localizing RNAi pathway polypeptides in tissue sections or fractionated cell preparations, determining whether an RNAi pathway gene is expressed (e.g., after transfection with an RNAi pathway gene), and evaluating the expression of an RNAi pathway gene in disorders (e.g., genetic conditions) where the RNAi pathway may be affected.

An isolated RNAi pathway protein (e.g., RDE-1), or a portion or fragment thereof, can be used as an immunogen to generate antibodies that bind to an RNAi pathway protein using standard techniques for polyclonal and monoclonal antibody preparation. The RNAi pathway immunogen can also be a mutant RNAi pathway protein or a fragment of a mutant RNAi pathway protein. A full-length RNAi pathway protein 30 can be used or, alternatively, antigenic peptide fragments of RNAi pathway protein can be used as immunogens. The antigenic peptide of an RNAi pathway protein comprises at

least 8 (preferably 10, 15, 20, or 30) amino acid residues. In the case of RDE-1, these residues are drawn from the amino acid sequence shown in SEQ ID NO:3 and encompass an epitope such that an antibody raised against the peptide forms a specific immune complex with RDE-1. Preferred epitopes encompassed by the antigenic pentide are 5 regions of the protein that are located on the surface of the protein, e.g., hydrophilic regions.

An RNAi pathway protein immunogen typically is used to prepare antibodies by

immunizing a suitable subject (e.g., rabbit, goat, mouse or other mammal) with the immunogen. An appropriate immunogenic preparation can contain, for example, recombinantly expressed RNAi pathway protein or a chemically synthesized RNAi polypeptide. The preparation can further include an adjuvant, such as Freund's complete or incomplete adjuvant, or similar immunostimulatory agent. Immunization of a suitable subject with an immunogenic RNAi pathway protein preparation induces a polyclonal anti-RNAi pathway protein antibody response.

10

15

Polyclonal antibodies that recognize an RNAi pathway protein ("RNAi pathway antibodies") can be prepared as described above by immunizing a suitable subject with an RNAi pathway protein immunogen. The RNAi pathway antibody titer in the immunized subject can be monitored over time by standard techniques, such as with an enzymelinked immunosorbent assay (ELISA) using immobilized RNAi pathway protein from 20 which the immunogen was derived. If desired, the antibody molecules directed against the RNAi pathway protein can be isolated from the mammal (e.g., from the blood) and further purified by well-known techniques, such as protein A chromatography to obtain the IgG fraction. At an appropriate time after immunization, e.g., when the RNAi pathway antibody titers are highest, antibody-producing cells can be obtained from the 25 subject and used to prepare monoclonal antibodies by standard techniques, such as the hybridoma technique originally described by Kohler and Milstein (1975) Nature 256:495-497, the buman B cell hybridoma technique (Kozbor et al. (1983) Immunol. Today 4:72), the EBV-hybridoma technique (Cole et al. (1985), Monoclonal Antibodies and Cancer Therapy, Alan R. Liss, Inc., pp. 77-96) or trioma techniques. The technology for producing hybridomas is well known (see generally Current Protocols in Immunology (1994) Coligan et al. (eds.) John Wiley & Sons, Inc., New York, NY). Briefly, an

immortal cell line (typically a myeloma) is fused to lymphocytes (typically splenocytes) from a mammal immunized with an RNAi pathway immunogen as described above, and the culture supernatants of the resulting hybridoma cells are screened to identify a hybridoma producing a monoclonal antibody that binds to the RNAi pathway protein.

5

Any of the many well known protocols used for fusing lymphocytes and immortalized cell lines can be applied for the purpose of generating a monoclonal antibody against an RNAi pathway protein (see, e.g., Current Protocols in Immunology, supra; Galfre et al., 1977, Nature 266:55052; R.H. Kenneth, in Monoclonal Antibodies: A New Dimension In Biological Analyses, Plenum Publishing Corp., New York, New 10 York, 1980; and Lerner, 1981, Yale J. Biol. Med., 54:387-402. Moreover, one in the art will appreciate that there are many variations of such methods which also would be useful. Hybridoma cells producing a monoclonal antibody of the invention are detected by screening the hybridoma culture supernatants for antibodies that bind to the RNAi pathway protein, e.g., using a standard ELISA assay.

15 Alternative to preparing monoclonal antibody-secreting hybridomas, a monoclonal RNAi pathway antibody can be identified and isolated by screening a recombinant combinatorial immunoglobulin library (e.g., an antibody phage display library) with an RNAi pathway protein to thereby isolate immunoglobulin library members that bind to the RNAi pathway protein. Kits for generating and screening 20 phage display libraries are commercially available (e.g., the Pharmacia Recombinant Phage Antibody System, Catalog No. 27-9400-01; and the Stratagene SurfZAPTM Phage Display Kit, Catalog No. 240612). Additionally, examples of methods and reasents particularly amenable for use in generating and screening antibody display library can be found in, for example, U.S. Patent No. 5,223,409; PCT Publication No. WO 92/18619; 25 PCT Publication No. WO 91/17271; PCT Publication No. WO 92/20791; PCT Publication No. WO 92/15679; PCT Publication No. WO 93/01288; PCT Publication No. WO 92/01047; PCT Publication No. WO 92/09690; PCT Publication No. WO 90/02809; Fuchs et al., 1991, Bio/Technology 9:1370-1372; Hay et al., 1992, Hum. Antibod. Hybridomas 3:81-85; Huse et al., 1989, Science 246:1275-1281; Griffiths et al., 1993. 30 EMBO J. 12:725-734.

Techniques developed for the production of "chimeric antibodies" (Morrison et al., Proc. Natl. Acad. Sci. USA, 81:8851, 1984; Neuberger et al., Nature, 31:4654, 1984; Takeda et al., Nature, 31:4652, 1984) can be used to agilice the genes from a mouse antibody molecule of appropriate antigen specificity together with genes from a human 5 antibody molecule of appropriate biological activity. A chimeric activody is a molecule in which different portions are derived from different animal species, such as those having a variable region derived from a murine mAb and a human immunoglobulin constant region.

Alternatively, techniques described for the production of single chain antibodies (U.S. Patent. 4)46,778; and U.S. Patents 4)46,778 and 4,704,692) can be pdapted to produce single chain antibodies against an RN41 pathway protein or polypeptide. Single chain antibodies are formed by linking the heavy and light chain fragments of the Fv region via an autino acid brider, resulting in a single chain ordomeristic chain produced in the contraction of the contraction of the chain produced in the chain solvenity.

Antibody fragments that recognize and bind to specific epitopes can be generated by known techniques. For example, such fragments can include but are not limited to F(st)<sup>2</sup>/<sub>2</sub> fragments. which can be produced by peption digestion of the autibody molecule, and Fab fragments, which can be generated by reducing the disulfide bridges of F(st)<sup>2</sup>/<sub>2</sub> fragments. Alternatively, Fab expression libraries can be constructed (Huse et al., Science, 246:1275, 1989) to allow rapid and easy identification of monoclonal Fab fragments with the desired specificity.

# Identification of RNAi Pathway Components

30

RNAi pathway components can be identified in C. elegans and other animals (e.g., a mammal) using the methods described in the Examplea below. Pathway components can also be identified using methods known in the art and the information provided herein. Such components include those involved in protein-protein and protein:RNA interactions. Specifically, RDE-1 can be used to identify additional proteins and RNA molecules that bind to the RDE-1 protein and so facilitate genetic interference.

The RNAi pathway mutant strains described herein (e.g., rde-1, rde-2, rde-3, rde-4, and rde-5; also mut-2 and mut-7) can be used in genetic screens to identify additional

RNAi pathway components. For example, a strain deficient for rds-1 activity can be mutagenized and screened for the recovery of genetic interference. This type of screen can identify allele-specific suppressors in other genes or second site mutations within the rds-1 gene that restore its activity. The resulting strains may define new genes that activate RNAi to overcome or bypass the rds-1 defect. The mutations identified by these methods can be used to identify their corresponding gene sequences.

Two-hybrid screems can also be used to identify proteins that bind to RNAi pathway proteins such as RDE-1. Genes encoding proteins that interact with RDE-1 or human homology of the C. eleganz RDE-1, are identified using the two-hybrid method [O [Fields and Song, 1989, Nature 340;245-246; Chien et al., 1991, Proc. Natl. Acad. Sci. USA 88-9578-9582; Fields and Sternglanz, 1994, Trends Genet. 10:286-292; Bartel and Fields, 1995, Marthod Ensymol. 254-241-263). DNA encoding the RDE-1 protein is closed and expressed from plasmids harboring GALA or lexA DNA-binding domains and co-mansformed into cells harboring laz. and HB3 reporter constructs along with libraries of cDNAs that have been closed into plasmids harboring the GALA activation domain. Libraries used for such co-transformation include those made from C. eleganz or a vertebrate ambronoic cell.

#### Mechanisms of Action of RNAi Pathway Components

20

Specific cellular functions associated with the RNAi pathway include the specific targeting of a mucleic acid by a drkNA, uptake of drkNAi, transport of drkNA, amplification of the drkNA signal, and genetic interference. The mechanism of interference may involve translation inhibition, or interference with RNA processing. In addition, direct effects on the corresponding gene may contribute to interference. These mechanisms can be identified investigated using the methods described herein and methods known in the art.

#### Methods of Screening for Molecules that Inhibit the RNAi Pathway

The following assays are designed to identify compounds that are effective

inhibitors of the RNAi pathway. Such inhibitors may act by, but are not limited to,
binding to an RDE-1 polypeptide (e.g., from C. elegans, mouse, or human), binding to

intracellular proteins that bind to an RNAi pathway component, compounds that interfere with the interaction between RNAi pathway components including between an RNAi pathway component and a dsRNA, and compounds that modulate the activity or expression of an RNAi pathway gene such as rde-1. An inhibitor of the RNAi pathway 5 can also be used to promote expression of a transgene,

Assays can also be used to identify molecules that bind to RNAi pathway gene regulatory sequences (e.g., promoter sequences), thus modulating gene expression. See, e.g., Platt, 1994, J. Biol. Chem. 269:28558-28562, incorporated herein by reference in its entirety

The compounds which may be screened by the methods described herein include, but are not limited to, peptides and other organic compounds (e.g., peptidomimetics) that bind to an RNAi pathway protein (e.g., that bind to an RDE-1), or inhibit its activity in any way.

10

20

25

Such compounds may include, but are not limited to, peptides; for example, 15 soluble pentides, including but not limited to members of random pentide libraries: (see. e.g., Lam et al., 1991, Nature 354:82-94; Houghten et al., 1991, Nature 354:84-86), and combinatorial chemistry-derived molecular libraries made of D-and/or L-amino acids. phosphopeptides (including, but not limited to, members of random or partially degenerate, directed phosphopeptide libraries; see e.g., Songyang et al., 1993, Cell 72:767-778), and small organic or inorganic molecules.

Organic molecules are screened to identify candidate molecules that affect expression of an RNAi pathway gene (e.g., rde-1), e.g., by interacting with the regulatory region or transcription factors of a gene. Compounds are also screened to identify those that affect the activity of such proteins, (e.g., by inhibiting rde-I activity) or the activity of a molecule involved in the regulation of, for example, rde-1.

Computer modeling or searching technologies are used to identify compounds, or identify modifications of compounds that modulate the expression or activity of an RNAi pathway protein. For example, compounds likely to interact with the active site of a protein (e.g., RDE-1) are identified. The active site of an RNAi pathway protein can be identified using methods known in the art including, for example, analysis of the amino acid sequence of a molecule, from a study of complexes of an RNAi pathway, with its

native ligand (e.g., a dsRNA). Chemical or X-ray crystallographic methods can be used to identify the active site of an RNAi pathway protein by the location of a bound ligand such as a dsRNA.

The three-dimensional structure of the active site is determined. This can be done

suing known methods, isoluding X-ray crystallography which may be used to determine
a complete molecular structure. Solid or liquid phase NMR can be used to determine
certain intra-molecular distances. Other methods of structural analysis can be used to
determine partial or complete geometrical structures. Geometric structure can be
determined with an RNAi pathway precein bound to a natural or ertificial ligand which
may provide a more accurate active site structure determination.

Computer-based numerical modeling can also be used to predict protein structure (especially of the active site), or be used to complete an incomplete or insufficiently accurate structure. Modeling methods that may be used are, for example, parameterized models specific to particular biopolymers such as proteins or nucleic acids, molecular dynamics models based on computing molecular motions, statistical mechanics models based on thermal ensembles, or combined models. For most types of models, standard molecular frore fields, representing the forces between constituent storms and groups are necessary, and can be selected for the model from among the force fields known in physical chemistry. Information on incomplete or less accurate structures determined as a solution of the structure computed by these modeling methods.

Having determined the structure of the active site of an RNAsi pathway protein (e.g., RDP-1), either experimentally, by modeling, or by a combination of methods, considiate modulating compounds are leidentified by searching databases contaming compounds and the leidentified by searching databases contaming compounds along with information on their molecular structure. The compounds identified in such a search are floss that have structures that match the active site structure, fit into the active site, or interact with groups defining the active site. The compounds identified by the search are potential RNAsi pathway modulating compounds.

These methods may also be used to identify improved modulating compounds from an already known modulating compound or ligand. The structure of the known compound is modified and effects are determined using experimental and computer

modeling methods as described above. The altered structure may be compared to the active site structure of an RNAi pathway protein (e.g., an RDE-1) to determine or predict how a particular modification to the ligand or modulating compound will affect its interaction with that protein. Systematic variations in composition, such as by varying 5 side groups, can be evaluated to obtain modified modulating compounds or ligands of unefferred noefficitive or activity.

Other experimental and computer modeling methods useful to identify modulating compounds based on identification of the active sites of an RNAi pathway protein and related transduction and transcription factors will be apparent to those of skill in the art.

Examples of molecular modeling systems are the QUANTA programs, e.g., CHARMm, MCSS/HOOK, and X-LIGAND, (Molecular Simulation, Jac., San Diego, CA). QUANTA analyzes the construction, graphic modeling, and analysis of molecular structure. CHARMm analyzes senegy minimization and molecular dynamics functions. MCSS/HOOK characterizes the ability of an active site to bind a ligand using energetics calculated via CHARMm. X-LIGAND fits ligand molecules to electron density of protein-ligand complexes. It also allows interactive construction, modification, visualization, and analysis of the behavior of molecules with each other.

10

30

Articles reviewing computer modeling of compounds interacting with specific protein can provide additional guidance. For example, see Rotivinen et al., 1988, Actar Pharmaceutical Fennica 97:159-166; Ripka, New Scientist June 16, 1988 pp.54-57; McKinaly and Rossmann, 1989, Ann. Rev. Pharmacol. Toxicol. 29:111-122; Perry and Davies. OSAR Quantitative Structure -Accitivity Relationships in Drug Design pp. 189-193 (Alan R. Liss, Inc., 1989); Lewis and Deam, 1989, Proc. R. Soc. Lond. 236:125-140, 251-141-132; and, regarding a model receptor for nucleic acid components, Askew et al., Art. J. Chem. Soc. 111:1022-1090. Computer programs designed to screen and depict chemicals are available from companies such as MSI (supra), Allelix, Inc. (Mississauga, Ontario, Canada), and Hypercube, Inc. (Gaineaville, FL).

These applications are largely designed for drugs specific to particular proteins; however, they can be adapted to the design of drugs specific to identified regions of DNA or RNA. Chemical libraries that can be used in the protocols described herein include

those available, e.g., from ArQule, Inc. (Medford, MA) and Oncogene Science, Inc. (Uniondale, NY).

In addition to designing and generating compounds that alter binding, as described above, libraries of known compounds, including natural products, synthetic 5 chemicals, and biologically active materials including peptides, can be screened for compounds that are inhibitors or activators of the RNAi pathway components identified herrin.

Compounds identified by methods described above can be used, for example, for claborating the biological function of RNAi pathway gene products (e.g., un RDE-1), and to treat genetic disorders involving an RNAi pathway protein. Assays for testing the effectiveness of compounds such as those described herein are further described below.

# In vitro Screening Assays for Compounds that Bind to RNAi Pathway Proteins and Genes

15 In vitro systems can be used to identify compounds that interact with (e.g., bind to) RNAI pathway proteins or genes encoding those proteins (e.g., r, rdo-1 and its protein product). Such compounds are useful, for example, for modulating the activity of these entities, claborating their biochemistry, treating disorders in which a decrease or increase in draRNA mediated genetic interference is desired. Such compounds may also be useful to treat diseases in animate, specially humans, inwolving enematedes, e.g. trichinosis, trichuriasis, and toxocariasis. Compounds such as those described herein may also be useful to treat plant diseases caused by semantedes. These compounds can be used in screens for compounds that disrupt normal function, or may themselves disrupt normal function.

25 Assays to identify compounds that bind to RNAi pathway proteins involve preparation of a reaction mixture of the protein and the test compound under conditions sufficient to allow the two compouents to interact and bind, thus forming a complex which can be removed and/or detected.

Screening assays can be performed using a number of methods. For example, an

RNAi pathway protein from an organism (e.g., RDE-1), peptide, or fusion protein can be
immobilized onto a solid phase, reacted with the test compound, and complexes detected

by direct or indirect labeling of the test compound. Alternatively, the test compound can be immobilized, reacted with the RNAi pathway molecule, and the complexes detected. Microfiter plates may be used as the solid phase and the immobilized component anchored by covalent or noncovalent interactions. Non-covalent attachment may be 5 achieved by conting the solid phase with a solution containing the molecule and drying. Alternatively, an antibody, for example, one specific for an RNAi pathway protein such as RDE-1 is used to anchor the molecule to the solid surface. Such surfaces may be prepared in advance of use, and stored.

In these screening assays, the non-immobilized component is added to the coated or surface containing the immobilized component under conditions sufficient to permit interaction between the two components. The uneasted components are then removed (e.g., by washing) under conditions such that say complexes formed will remain immobilized on the solid phase. The detection of the complexes may be accomplished by a number of methods known to those in the art. For example, the nonlimmobilized of component of the assay may be petabeled with a nadioactive or enzymatic entity and detected uniang appropriate means. If the non-immobilized entity was not prelabeled, an indirect method is used. For example, if the non-immobilized entity is an RDE-I, an antibody against the RDE-I is used to detect the bound molecule, and a secondary, labeled antibody used to detect the entire complex.

Alternatively, a reaction can be conducted in a liquid phase, the reaction products separated from unreacted components, and complexes detected (e.g., using an immobilized antibody specific for an RNAi pathway protein).

20

Cell-based assays can be used to identify compounds that intenet with RNAi pathway proteins. Cell lines that naturally express such proteins or have been genetically engineered to express such proteins (e.g., by transfection or transduction of an rds-1 DNA) can be used. For example, text compounds can be administered to cell cultures and the amount of mRNA derived from an RNAi pathway gene analyzed, e.g., by Northern analysis. An increase in the amount of RNA transacribed from such a gene companed to control cultures that did not contain the text compound indicates that the text of compound is an inhibitor of the RNAi pathway. Similarly, the amount of a polypeptide encoded by an RNAi auditway energ, or the activity of such as an observation can be notived.

in the presence and absence of a test compound. An increase in the amount or activity of the polypeptide indicates that the test compound is an inhibitor of the RNAi pathway,

#### Ectopic Expression of an RNAi Pathway Gene .

5

Ectopic expression (i.e., expression of an RNAi pathway gene in a cell where it is not normally expressed or at a time when it is not normally expressed) of a mutant RNAi pathway gene (i.e., an RNAi pathway gene that suppresses genetic interference) can be used to block or reduce endogenous interference in a host organism. This is useful, e.g., for enhancing transgene expression in those cases where the RNAi pathway is interfering 10 with expression of a transgene. Another method of accomplishing this is to knockout or down regulate an RNAi pathway gene using methods known in the art. These methods are useful in both plants and animals (e.g., in an invertebrate such as a nematode, a mouse, or a human).

Ectonic expression of an RNAi pathway gene, e.g., rde-I or rde-4 can also be 15 used to activate the RNAi pathway. In some cases, targeting can be used to activate the pathway in specific cell types, e.g., tumor cells. For example, a non-viral RNAi pathway gene construct can be targeted in vivo to specific tissues or organs, e.g., the liver or muscle, in patients. Examples of delivery systems for targeting such constructs include receptor mediated endocytosis, liposome encapsulation (described below), or direct 20 insertion of non-viral expression vectors.

An example of one such method is liposome encapsulation of nucleic acid. Successful in vivo gene transfer has been achieved with the injection of DNA, e.g., as a linear construct or a circular plasmid, encapsulated in liposomes (Ledley, Human Gene Therapy 6:1129-1144 (1995) and Farhood, et al., Ann. NY Acad. Sci. 716:23-35 (1994)). 25 A number of cationic liposome amphiphiles are being developed (Ledley, Human Gene Therapy 6:1129-1144 (1995); Farhood, et al., Ann. NY Acad. Sci., 716:23-35 (1994) that can be used for this purpose.

Targeted gene transfer has been shown to occur using such methods. For example, intratracheal administration of cationic lipid-DNA complexes was shown to 30 effect gene transfer and expression in the epithelial cells lining the bronchus (Brigham, et al., Am. J. Respir. Cell Mol. Biol. 8:209-213 (1993); and Canonico, et al., Am. J. Respir.

Cell Mol. Biol. 10:24-23 (1994)). Expression in pulmonary tissues and the endothelium was reported after intravenous injection of the complexes (Brigham, et al., Am. J. Respir. Cell Mol. Biol. 8:209-213 (1995); Zhu, et al., Seinece, 26:1:209-211 (1993); Siewart, et al., Human Gene Therapy 3:267-275 (1992); Nisbel, et al., Human Gene Therapy 3:569-565 (1992); and Canantion, et al., J. Appl. Physiol. 77:415-419 (1994)). An expression cassette for an RNA1 pathway sequence in linear, plasmid or viral DNA forms can be condensed through ionic interactions with the cationic ligid to form a particulate complex for hv hv deldvery (Stewart, et al., Human Gene Herapy 3:267-225 (1992)).

Other liposome formulations, for example, proteotiposomes which contain viral cavelope receptor proteins, i.e., virosomes, have been found to effectively deliver genes into hepstocytes and lédoby cells after direct injection (Nicolau, et al., Proc. Natl. Acad. Sci. USA 80:1068-1072 (1993); Kameda, et al., Science 243:375-378 (1989); Mannino, et al., Biocheniques-6:682 (1988); and Tomifa, et al., Biochem. Biophys. Res. Comm. 1861:20:134 (1992)).

Direct injection can also be used to administer an RNA1 pathway nucleic acid copurate in a DAA expression vectors, e.g., into the muscle or liver, either as a solution or as a calcium phosphate precipitate (Wolff, et al., Science 247:1465-1466 (1990); Aacedi, et al., The New Biologist 3:71-81 (1991); and Benvenisty, et al., Proc. Natl. Acad. Sci. USA 43:9551-9555 (1992).

# Preparation of RNAi Agents

15

20

RNAI pathway components can be used to prepare RNAI aparts. Such agents are dranks at that have been treated with RNAI pathway components rendering the treated drkRNA expaile of activity in the RNAI pathway and can be used as sequence-specific interfering agents useful for tampreted genetic interference. Specifically, treating a drkRNA with an RDE-1 and RDE-4 in uneful for making an RNAI agent and RNAI agent are produced by prefincionisting a drkRNA are vitro in the presence of RDE-1 and RDE-4.

Another method of preparing an RNAi agent is to activate the RNAi pathway in a target cell (i.e., a cell in which it is desirable to activate the RNAi pathway such as a tumor cell) by transgenesis of an rde-1 coding sequence and an rde-4 coding sequence into the target cell.

RNAi pathway polypeptides can be modified, e.g., to enhance their stability or cellular uptake, by attaching lipophilic or other helper groups to the polypeptide, by the formation of chimeras with proteins or other moieties that are taken up by cells, or by the use of liposomes or other techniques of drug delivery known in the art.

In C. elegans, RNAi agents appear to spread from cell to cell, thus, active RNAi agents can diffuse or be actively transported from conditioned media or serum directly into target cells. Alternatively, RNAi agents can be injected into an organism or cell. They may also be incorporated into a cell using liposomes or other such methods known in the art

Such methods are useful for stimulating the RNAi pathway in C. elegans cells. and in heterologous cells including plants and vertebrate cells. Such methods are useful in mammalian, e.g., human cells,

#### Enhanced Delivery of a Cargo Compound

5

. 10

15

30

RNAi pathway components that mediate the transport of dsRNA into cells and tissues can be used to promote the entry of dsRNA into cells and tissues, including dsRNA that is linked to another compound. The method is accomplished by linking dsRNA to a cargo compound (e.g., a drug or DNA molecule), e.g., by a covalent bond. The endogenous RNAi pathway gene expressing dsRNA transport function is activated 20 using methods known in the art. Alternatively, other methods can be used such as transfecting the target cell with the gene that affects transport thus permitting the cell or tissue to take up the dsDNA.

#### Examples

25 The invention is further described in the Examples below which describe methods of identifying mutations in the RNAi pathway and methods of identifying genes encoding components of the RNAi pathway.

#### Example 1: Strains and Alleles

The Bristol strain N2 was used as standard wild-type strain. The marker mutations and deficiencies used are listed by chromosomes as follows: LGI: dov-

14(e188), unc-13(e51); LGIII: dpp-17(e164), unc-32(e189); LGV: dpp-12(e224), unc-42(e270), daf-11(m27), e191, m193, n1931, n2931, n2935, mc-76(e911). The C. elegans strain DP13 was used to generate hybrids for STS linkage-mapping (Williams et al., 1992; Genetics 131 s/06-6524).

Sensitivity to RNAi was tested in the following strains. MT3126: mus-2(r439) (obtained from Joho Colliss, Department of Biochemistry & Molecular Biology, University of New Hampshire, Durham, MH; dpp-196/1347), TW410:mus-2(r439) sem-4/n13730, ML917: mus-7/p8/2040, SSS52: mes-2/m76/ rol-1/e01/mrof (obtained from S. Strome, Biology Dept., Indiana University), SS449: mes-3(m88) dpp-5(e61) (from S.

10 Strome, supra); hDp:20, SS268: dpp-11(e224) mes-4(bn23) unc-76(e911)/nT1, SS360: mes-6(bn60) dpp-20(e1202)/nT1, CB879: him-1(e379). A non-Une mu-6 strain used was derived from NW1096: mus-6(st702) unc-22(st192::Tc1), due to the loss of Tc1 insertion in unc-22.

Homozygous mutants of mus-6, mes-2, 3, 4, 6 and him-1 showed sensitivity to 18 RNAi by injection of pos-1 daRNA. The dose of injected RNA was about 0.7mg/ml.

This dose lies within the range where reduced concentration leads to reduced interference effects. The results of the injection of pos-1 daRNA into these mutants (dead embryos / F1 progeny) were as follows: mus-6: 422437, mes-2: 781/87, mes-3: 462/474, mes-4: 810/814, mes-6: 9001/00.2 htm: 241/4248. RJ controll: 365/93-2.

To test mutator activity, a mutant that was caused by To4 transposon insertion was used; TR1175: une-22/765::To4). Strains TW410 and TR1175 were gifts from Q. Boese and J. Collins (Department of Biochemistry & Molecular Biology, University of New Hampshire, Durham, NH).

#### 25 Example 2: RNA interference assay

411, Japan).

20

Genetic interference using RNAi administered by microinjection was performed as described in Fire et al., 1987, apper and Rochelsene et al., 1997, Cell 90:707-716. por-I cDNA closo ylc61b1, pur-2 cDNA close yk96a7, apr-3 cDNA close yk752 were used to prepare daRNA in wire. These cDNA closes were obtained from the C. elegams 20 cDNA project Y. Kohtara, Gene Network Lab, National Institute of Genetics, Michina 10 cDNA project Y. Kohtara, Gene Network Lab, National Institute of Genetics, Michina 10 cDNA project Y. Kohtara, Gene Network Lab, National Institute of Genetics, Michina 10 cDNA project Y. Kohtara, Genetics, Michina Institute of Genetics, Michina 10 cDNA project National Control of the Co

Genetic interference using RNAi administered by feeding was performed as described in Timmons and Fire, 1998, Namer 395:54. post - IONA was cloned into a plasmid that contains two T7 promoter sequences arranged in bead-to-head configuration. The plasmid was transformed into an E-coll stania, BLZ1(DE3), and the transformed 5 bacteria were seeded on NGM (nematode growth medium) plantes containing 60µg/ml ampicillin and 80µg/ml BTG. The bacteria were grown certified at croom temperature to induce pos-1 datNA. Seeded plates (BLZ1(DE3)(datRNA) plates) proceed at \*C remained effective for inducing interference for up to two weeks. To test RNAi startistivity, C. elegants larvae were transferred onto BLZ1(DE3)(datRNA) plates and embryonic learnily was assessed in the next energated.

Transgenic lines expressing interfering RNA for nw-22 were engineered using a mixture of three plasmids: pPD[L4218] (nm-22 antisense segment, driven by npo-3 promoter); pPD[L4218] (corresponding nw-22 sense segment, driven by npo-3 promoter); pPD(L4218] (corresponding nw-22 sense segment, driven by npo-3 promoter); pRP4 (semidominant transformation marker). DNA concentrations in the injected mixture were 100µg/ml each. Injections were as described (Melio et al., 1991, EMBO J. 103599, Melio and Eric, 1995, Melio da Eric, 1881, 618, 648,511-881, 618, 648,511-881.

#### Example 3: Identification of RNAi-Deficient Mutants

15

A method of screening for mutants defective in the RNAi pathway was devised to that would permit the large-scale application of deRNA to mutagenized populations. Feeding worms E. coll which express a dsRNA, or simply soaking worms in dsRNA solution, are both sufficient to induce interference in C. elegours (Timmons and Tire, 1998, supra; Tabum et al., 1998, Science 282:430-431). To carry out a selection, the feeding method was optimized to deliver interfring RNA for an essential gene, pos. J. 25.

25. C. elegours hermaphrodites that ingest bottria expressing dsRNA corresponding to a segment of pos-1 are thenselves unaffected but produce dead embryos with the distinctive posse. J embryonic lettal phenotype.

To identify strains defective in the RNAi pathway, wild-type animals were mutagenized, backrossed, and the F2 generation consimed for rare individuals that were able to produce complete broads of visible progeny. Chemical mutagenesis was used to generate the mutations as well as spontaneous mutations arising in the mut-6 strain in

which Tel transposons are activated (Mori et al., 1988, Genetics 120:397-407). To facilitate screens for mutations, an egg laying, the starting strain was used. In the absence of egg laying, the F3 programy remained trapped within the mother's outrice. Candidate mutants had internally hatched broods of viable embryos and were thus easily

5 distinguished from the background population of individuals filled primarily with dead embryos (Figure 1A). Candidates were then re-tested for resistance to injected dsRNA.

The genetic screen used to isolate RNAi pathway mutants was similar to one designed by James R. Preiss for the identification of maternal effect mutants (Kemphues et al., 1988, Cell 52:311-320). An Egl strain, lin-2(e1309) was mutagenized with EMS

10 and the F2 generation was cultured on a beacterial lawn expressing pos-1 deRNA. Mutagenized populations were then societied in the individuals that were able to produce complete broods of visible progeny forming a distinctive "bag of worms" phenotype. To make sure that the animals were truly resistant to RNAi, candidate strains were next assayed for resistance to RNAi by injection. Independent EMS induced alleles of rela-1 were found in two separate pools of mutagenized mains at a frequency of support and the pool of the p

In addition, a search was made for spontaneous mutants using a mus-of strian in which Tel transposons are activated (Mori et al., 1988). 100,000 mut-d: lin-2 minnals (Mello et al., 1994) were cultured on bacteria expressing pos-1 daRNA. After coe generation of growth, surviving animals were transferred again to plates with bacteria expressing the dsRNA and screened for resistant mutants. Three resulting strains were genetically mapped. One of these strains (nx20) mapped to LGV and failed to complement rdc-1(nx210). Two strains nx299 and nx301 mapped to LGUII and define the rd-6 complementation group. Because the screen was closal in nature and involved rounds of enrichment it is most beful that both rds-4 strains are related.

Seven mutant strains were selected for genetic mapping. These seven mutants defined four complementation groups; rde-1, with three alleles, rde-4, with two alleles, and rde-2, and rde-3, with one allele each (Figure 1B).

To map the RNAi defective mutations, the RNAi resistant phenotype was assayed

either by feeding bacteria expressing pos-1 dsRNA or by injection of a dsRNA mixture of

pos-1 and unc-22. The same assays were used for complementation tests. In vivo

expression of une-22 dsRNA was also used for mapping of rde-1. Mapping with visible marker mutations was performed as described in Breaner (1974, Genetics, 77:71-94) and mapping with STS marker was performed as described in Williams et al. (1992, supra).

ne.1/9, ne.279 and ne.200 failed to complement each other, defining the rds-1 locus. rds-1 mutations mapped near une-d2 V. Three factor mapping was used to locate rds-1/ns-1000 one sighth of the distance from use-d2 in the use-d2/ds/21 linterval (G/A Unc-noc-Dat recombinants analyzed). The rds-1/ns-1000 allele complemented the chromosomal deficiency s/D/9 and failed to complement e/D, m/D/9, n/D/91 and s/D/95, rds-2/ns-2(1) m/D rds-1/ns-2009 mapped near use-d2 II rds-2 complemented rds-3: rds-4(ns-299) and (ns-201) mapped near use-d9 III and failed to complement each other. ms-299 complements ms-r/6-k2009

The rds-1(+) activity is sufficient maternally or zygotically. To test the maternal sufficiency, animals heterozygous for rde-1 (ne219) were injected with dsRNA targeting the zygotic gene, sqt-3, and self progeny were assayed for the Sqt phenotype. 100% of 15 the self progeny including rde-1 homozygous progeny were found to exhibit the Sot phenotype. Thus, maternally provided rds-1(+) activity is sufficient to mediate interference with a zygotic target gene. Zygotic sufficiency was assayed by injecting homozygous rde-1 mothers with dsRNA targeting the zygotic unc-22 gene (Figure 3). Injected animals were allowed to produce self-progeny or instead were mated after 12 hours to wild-type males, to produce heterozygous rde/+ cross-progeny. Each class of progeny was scored for the unc-22 twitching phenotype as indicated by the fraction shown if Figure 3 (Unc progeny/total progeny). The injected animals were then mated with wild-type males. Self progeny from homozygous injected mothers were unaffected, however, 68% of the cross progeny were Unc. This result indicates that zygotically provided rde-1(+) activity is also sufficient. However both maternal and zygotic rde-I(+) activity contribute to zygotic interference as 100% of progeny from wild-tyne injected mothers exhibit unc-22 interference (606/606), Thus, rde-1(+) and rde-4(+) activities are not needed for dsRNA uptake, transport or stability.

RNAi sensitivity of several existing C. elegans mutants was also examined. Most of these mutant strains were fully sensitive to RNAi. However, RNAi resistance was identified in two strains that had previously been shown to exhibit elevated levels of

transpason mobilization (mustator staine); mm-2 (described in Collins et al., 1987, Nature 328:726-728) and mut-7 (described in Ketting et al., Cell, in press for release on October 15, 1599). Another mustator strain, mu-6/gi/2021, was fully sensitive to RNAi. Since mustator strains continually accumulate mustations, the resistance of mut-2 and mut-7 may have been due to the presence of secondary mustations. To test this possibility we examined the genetic linkages between the mustator and RNAi resistance phenotypes of mut-2 and mut-7. We found that independently outcreased mus-2/e/459 mustator strains TW410 and MT3126 both showed resistance to RNAi. We mapped the RNAi resistance phenotypes of mut-7/gis209 to the center of linkage group III (Figure 11), the position 10 that had been defined for the mustator activity of mut-7/gis204 by Ketting et al. (supro). Together, these observations indicate that the RNAi resistance phenotypes of the mut-3 and mut-7 strains are genetically linked to their mutant exclusives. Antimals heterotygous for the rds and mut alleles were generated by crossing wild-type males with Uno-Rde or Uno-Nat hermaphrodites. The rds and mut mutations appeared to be simple recensive unustators with the exception of mut-2/e/33, which appeared to be weakly dominant.

These data demonstrate that some genes are non-essential (e.g., rde-1 and rde-4).

This method can be used to identify additional mutations in RNAi pathway genes.

# 20 Example 4: Identification of Properties of RNAi-Deficient Mutants

(Figure 2A).

25

30

Effects of rde mutations in germline and somatic tissues

Microinjection was used to assay the sensitivity of each rde strain to several

gemillie and ste required for proper embryonic development (Tabara et al., 1999, Development 126:1-11; Boyd et al., 1996, Development 122:2075-3084). All rde-strains tested (as well as mu-2 and mu-2 hybox dispatificant resistance to daRNA targeting of these germline-specific genes (Figure 2B), as well as to several other germline specific genes tested. The rde-3 data (asterisk in Figure 2B) includes a 10% non-specific embryonic lethild vensent in the rde-3 strain.

distinct dsRNA species. The pos-1 and par-2 genes are expressed in the maternal

To examine the effect of these mutations on genetic interference of somatically expressed genes, cells were injected with dsRNA targeting the cuticle collagen gene sat-3

and the body muscle structural gene une-22. aqt-3 hypomorphic mutants exhibit a short, dumpy body shape (dgy; van der Keyl et al., 1994, Der. Dyr. 2018:6-94). une-27 mutations exchile stevere paralysis with a delistorite body whiching hepotoxype (Moreman et al., 1986, Proc. Natl. Acad. Sci. USA 83:2379-2583). rde-1, rde-3, rde-4 and mut-2 strains showed strong resistance to both aqt-3 and une-22 distNA, while rde-2 and mut-7 strains showed partial resistance. Thus rde-2 and mut-7 appeared to be partially issue-or geos-specific in that they were required fire effective RNAI against germline but not somatically expressed genes. The rde-1, rde-3, rde-4, and mut-2 (+) activities appeared to be required for interference for all genes analyzed. The rde and mut strains differ from 10 one another in sensitivity to up-2 deRNA.

#### Effect of rde on transposon mobilization

The effect of rde mutations on transposon mobilization was examined. Two of the newly identified mutants, rde-2 and rde-3 exhibited a level of transposon activation similar to that of mut-7 (Table 1). In contrast, transposon mobilization was not observed in the presence of rde-1 or rde-4 (Table 1).

TABLE 1: TRANSPOSON MOBILIZATION AND MALE INCIDENCE IN rde AND mut STRAINS

Percentage of Non-Unc	Revertants
unc-22 (r765::Tc4)	0 (0/2000)

rde-3 (ne298)	7.8 (71/912)

# rde-4 (ne299) 5 X-chromosome loss

Mutator strains (including mut-2, mut-7) rde-2 and rde-3) exhibit a second phenotype: a high incidence of males reflecting an increased frequency of X-chromosome loss during meiosis (Collins et al., 1987, supra; Ketting et al., supra). This

0.24 (5/2055)

phenotype was observed in rde-2 and rde-3 strains, but not observed in the rde-1 and rde-4 strains which showed a wild-type incidence of males (Table 1).

A previously described gene-silencing process appears to act on transgenes in the germline of C. elegans. Although the silencing mechanisms are not well understood. 5 they are known to depend on the products of the senes mes-2, 3, 4 and 6 (Kelly and Fire. 1998, Development 125:2451-2456). To examine the possibility that the RNAi and germline transgene-silencing might share common mechanistic features, we first asked if the mes mutants were resistant to RNAi. We found normal levels of RNA interference in each of these strains. We next asked if RNAi deficient strains were defective in

10 transgene-silencing. Three strains were analyzed: mut-7(pk204), rde-1(ne219) and rde-2(ne221).

To analyze transgene silencing in mut-7 worms, homozygous mut-7 lines carrying various GFP reporters transgenes were generated as follows: N2 (Bristol strain) males were mated to mut-7 (pk204) unc-32 (e189) hermaphrodites; cross progeny males were then mated to strains carrying the GFP transgenes. mut-7 unc-32/++ cross progeny from these matings were cloned, and mus-7 unc-32 homozygous animals carrying the transgenes were isolated from their self-progeny. After the GFP reporter transgenes were introduced into different genetic backgrounds, activation of GFP transgene expression in germ cells was assayed at 25 IIC by fluorescence microscopy. The tested GFP reporter 20 transgenes were each active in some or all somatic tissues, but had become silenced in the germline. The plasmids used and transgene designations are as follows: 1) nBK48 which contains an in-frame insertion of GFP into a ubiquitously expressed gene, let-858 (Kelly, et al., 1997, Genetics 146:227-238). ccExPD7271 contains more than 100 copies of pBK48 in a high copy repetitive array that is carried extrachromosomally. 2) nTH3 92 is an in-frame fusion of GFP with the maternal pie-1 gene (M. Dunn and G. Sevdony. Johns Hopkins University, Baltimore, MD), ihEx1070 carries pJH3.92 in a low conv "complex" extrachromosomal array generated by the procedure of Kelly et al. (1997. supra) pJKL380.4 is a fusion of GFP with the C. elegans nuclear laminin gene. lam-1. which is expressed in all tissues (J. Liu and A. Fire). ccln4810 carries pJKL380.4 in a 30 complex array that has been integrated into the X chromosome by gamma irradiation

using standard techniques.

The nun-7 strain was analyzed most extensively and was found to exhibit desilencing of three different germline transgenes tested (Table 2). The rde-2 strain exhibited a similar level of desilencing for a single transgene. In contrast, no transgene desilencing was observed in rds-1 mutants (Table 2). Thus, rms-7 and rds-2 which differ from rds-1 in having transposon mobilization and a high incidence of X-chromosome loss also differ from rds-1 in their ability to partially reactivate sitest germline transgenes.

TABLE 2: REACTIVATION OF SILENCED TRANSGENES IN THE GERMLINE OF nut-7(pk204)

Genetype	Transgene Array Percentage o Germline Desilencing

15 Example 5: Requirement for rale-I(+) and rde-4(+) Activities in Target Tissue
The rde-I and rde-4 mutants differ from other RNAi deficient strains identified
herein in that they do not cause transposon mobilization nor do they cause chromosome.

loss. The role of these genes in upstream events such as daRNA uptake, transport or stability was examined. Such events could be required for interference induced by ecogenous trainger RNAs but might be dispensable for natural functions of RNAsi. To evaluate these upstream events, rde-1 and rde-4 homozygotes were exposed to dsRNA. To evaluate these upstream events, rde-1 and rde-4 homozygotes were exposed to dsRNAs injected into the insential calls of homozygous rale and rde-6 homphordise and the injected animals were then mated to wild-type males (Figure 3). The self-progeny for both strains exhibited no interference with the targeted gene. However, there was potent interference in the rde-1/4 and rde-4 from sprongy (Figure 3). These observations indicated that rde-1 and rde-4 moutants have intact mechanisms for transporting the interference effect from the site of injection (the intestine) into the embryos of the injected animal and then into the issues of the resulting progeny. The stability of the resulting interference also appeared to be normal in rdg-1 and rde-4 as the homozygous injected mouters continued to produce affected cross progeny for several days after the time of finjection.

To examine whether rale-I and rale-I mutants could block interference enused by disRNA expressed directly in the target tissue, the muscle-specific promoter from the myo-I gene (Dibb et al., 1989, J. Mol. Biol. 203-509-5613) was used to drive the expression of both strands of the muscle structural gene use-2 in the body well muscles (Moorman et al., 1986, nyrar; Fire et al., 1991, Development 113-503-514). Another of three plasmids was injected: (Inyo-3 promoter-uso-2 antissemb, [nyo-3-uso-22 sense), and a marker plasmid (gRe4(nol-6qual006(pf)) [Mello et al., 1991]). Frequencies of Unctransgenic animals were followed in F1 and F2 generations. The \*Unc phenotype was weak. Wild-type animals becaring this transgene exhibit a strong twicking phenotype was weak. Wild-type animals becaring this transgene exhibit a strong twicking phenotype of the consistent with suc-22 interference. The twitching phenotype was strongly suppressed by both rale-1 and rale-4 mutants (Table 3). The mar-7 and rale-2 mutants which are benefits to suc-22(RMA) by microsingetions were also sensitive to promoter driven non-22 interference in the muscle (Table 3). Taken together these findings suggest that rale-1/19 and rale-4(rs) activities are not necessary for uptake or stability of the interfering NRA and man function directly in the target tissue.

#### Example 6: Molecular Identification of the rde-1 Gene

The risk-1 gene was closed using standard genetic mapping to define a physical partic interval likely to contain the gene using YACs and contaids that rescue risk-1 mutants. These were used to identify a closed risk-1 cDNA sequence and a closed risk-sequence. These methods can also be used to identify the genes for risk-2, risk-3, and risk-5 using the mutant strains provided herein.

To clone an rule-1 gene, yeast artificial chromosome clones (YACs) containing C.
elegans DNA from this interval were used to rescue the rule-1 mutant phenotype. To
15 facilitate this analysis candidate reacining YACs were co-injected with plasmids designed
to express ws-22(RNAs). YAC and cosmid clones that mapped near the rule-1 locus
were obtained from A. Coulson. rule-1/mc139 was rescued by YAC clones: Y97CL2 and
Y50BS. The two overlapping YAC clones provided rule-1 reacining activity as indicated
by unr-22 genetic interference with characteristic body paralysis and twitching in the F1
20 and F2 transgenic animals. In contrast a non-overlapping YAC clone failed to rescue
resulting in 100% non-whitching transeenic straines (Fizure 4A).

The rescuing activity was further localized to two overlapping cosmid clones, cosmid C27H6 and T10A5, and finally to a single 4.5kb genomic PCR fragment predicted to contain a single gene, designated K08H10.7 (RSQ ID NO1; Figures 5A-5C) The K08H10.7 PCR product gave strong rescue when amplified from wild-type genomic DNA. This rescue was greatly diminished using a PCR fragment amplified from any of the three rds-1 alleles and was abolished by a 4-bp insertion at a unique Nhel site in the rds-1 coding region. A wild-type PCR product from an adjacent gene C27H6.4, also fulled to rescue.

The K08H10.7 gcne from each of the rde-I mutant strains was sequenced, and distinct point mutations were identified that are predicted to after coding sequences in K08H10.7 (Figure 4A). Based on these findings rde-I can be identified as the K08H10.7 cene.

A full-length cDNA sequence was determined for rde-1 using the cDNA clones, yk296b10 and yk595b5. cDNA clones for rde-1 were obtained from Y. Kohara (Gene

Network Lab, National Institute of Genetics, Mishima 411, Japan). The cDNA sequence of coding region and 3'UTR was determined on yk296b10 except that the sequence of 5'UTR was determined on yk595h5. The GenBank accession number for rde-1 cDNA is AF180730 (SEQ ID NO:2). The rde-I cDNA sequence was used to generate a predicted translation product (SEQ ID NO:3), referred to as RDE-1, consisting of 1020 amino 20 acids. The RDE-1 sequence was used to query Genbank and identify numerous related genes in C. elegans as well as other animals and plants. This gene family includes at least 23 predicted C. elegans genes, several of which appear to be members of conserved subfamilies. Within subfamilies, conservation extends throughout the protein and all family members have a carboxy-terminal region that is highly conserved (Figure 4B). 25 Besides the genes shown in Figure 4B, other related genes include ARGONAUTE 1(Arabidopsis), SPCC736.11(S. pombe), and Piwi (Drosophila). A portion of the N terminal region of RDE-1 showed no significant similarity to any of the identified related genes. There are no defined functional motifs within this gene family. but members including RDE-1 are predicted to be cytoplasmic or nuclear by PSORT 30 analysis (Nakai and Horton, 1999, Trends Biochem. Sci. 24:34-36). Furthermore, one

family member named eIF2C has been identified as a component of a cytoplasmic

WO 01/20059 PCT/US00/28470

protein fraction isolated from rabbit reticulocyte lysates. The RDF-1 protein is most similar to the rabbit eIF2C. However, two other C. elegans family members are far more similar to eIF2C than is RDE-1 (Figure 4B). RDE-1 may provide sequence-specific inhibition of translation initiation in response to dsRNA.

5

The rde-I mutations appear likely to reduce or eliminate rde-1(+) activity. Two rde-1 alleles ne219 and ne297 are predicted to cause amino acid substitutions within the RDE-1 protein and were identified at a frequency similar to that expected for simple lossof-function mutations. The rde-1(ne219) lesion alters a conserved glutamate to a lysine (Figure 4B). The rde-1(ne297) lesion changes a non-conserved glycine, located four 10 residues from the end of the protein, to a glutamate (Figure 4B). The third allele, ne300, contains the strongest molecular lesion and is predicted to cause a premature stop codon prior to the most highly conserved region within the protein (Q>Ochre in Figure 4B). Consistent with the idea that rde-1 (ne300) is a strong loss of function mutation, we found that when placed in trans to a chromosomal deficiency the resulting deficiency trans-15 heterozyotes were RNAi deficient but showed no additional phenotypes. These observations suggest that rde-I alleles are simple loss-of-function mutations affecting a gene required for RNAi but that is otherwise non-essential.

Because of its upstream role RNA interference (see Examples 8-10 below), the RDE-1 protein and fragments thereof can be used to prepare dsRNA that is useful as an 20 RNAi agent.

#### Example 7: Maternal Establishment and Paternal Transmission of RNAi

To examine whether the interference effect induced by RNAi exhibited linkage to the target gene (e.g., was involved in a reversible alteration of the gene or associated chromatin), a strain was constructed such that the F1 males that carry the RNAi effect also bear a chromosomal deletion that removes the target gene (Fig. 7B). In the case of linkage to the target gene, the RNAi effect would be transmitted as a dominant factor.

In experiments testing the linkage of the interference effect to the target gene, three different species of dsRNA (pos-1 dsRNA, mom-2 dsRNA, or sgg-1 dsRNA) were 30 delivered into C, elegans in independent experiments. The dsRNA was delivered by injection through a needle inserted into the intestine. In general, dsRNA was synthesized

in vitro using T3 and T7 polymerases. Template DNA was removed from the RNA samples by DNase treatment (30 minutes at 37°C). Equal amounts of sense and antisense RNAs were then mixed and annealed to obtain daRNA. daRNA at a concentration of 1.5 mg/ml was injected into the intestine of animals. In control experiments, mixtures of linearized template DNA plasmids used for synthesizing RNA failed to induce interference in P0, F1, or F2 animals when injected into the intestine of hermaphrodites at a concentration of 0.2 mg/ml. Fig. 7A illustrates this experiment. The gond of the parent (P0) hermaphrodite has symmetrical anterior and posterior U-shaped arms as shown in Fig. 7A. Several fertilized eggs are shown in Fig. 7A, certally located in the uterus. The rentrallymal mature coopts are could up in the gond arms morp recriminal to the uterus. The embryos present in P0 at the time of injection gave rise to unaffected F1 progeny. Occytes in the proximal arms of the injected P0 gonds inherit the RNAi effect but also carry a flatfordout anternal maNA GF carriers of RNAi).

10

25

30

After a clearance period during which currier and unaffected F1 property are 
produced, the injected PO begins to exclusively produce dead F1 embryos with the 
phenotype corresponding to the inactivation of the gene targeted by the injected RNA 
(Tabus et al. 1999, Development 126:1; C. Rochelsen, 1997, Cell 90:707). Potential F1 
and F2 entries of the interference effect were identified within the brood of the injected 
animal. In the case of hermaphrodites, carriers were defined as "affected" if the animals 
produced at least 20% dead embryos with phenotypes corresponding to maternal loss of 
function for the targeted loss. In the case of males, entriers were defined as animals 
whose cross progeny included at least one affected F2 hermaphrodite. The total number 
of curriers identified in each generation for each of three daRNAs injected is shown in 
Fig. 7A as a fraction of the total number of animals assayed.

To examine the extragenic inheritance of RNAi, experiments were carried out investigating whether sperm that inherit the delicion and therefore have no copies of the target locus could carry the interference effect into the P2 generation. F1 males that carried both pas-1 (RNAi) and a chromosomal deficiency for the pas-1 locus were generated. The chromosome carrying the deficiency for pos-1 also carried a deficiency for phenotypically uncoordinated (unc). F2 progeny of the carrier male includes two genotypes: phenotypically with-type animals that inherit the (+) chromosome, and

phenotypically uncoordinated (Une) progeny that inherit the mDIS chromosome. In these experiments, the deficiency bearing sperm were just as capable as wild-type sperm of transferring interference to the F2 hermaphrodite progeny (Fig. 78). Thus, the target locus was not needed for inheritance of the interference effect.

5

20

25

Surprisingly, although males were sensitive to RNAi and could inherit and transmit RNAi acquired from their mothers, direct injections into males failed to cause transmission of RNAi to the F1 for several genes tested. In an example of this type of protocol, wild type males were injected with targeting dsRNA: body muscle structural gene unc-22, cuticle collagen gene sqt-3, maternal genes pos-1 and sgg-1. Males of the pes-10::gfp strain (Seydoux, G. and Dunn, MA, 1997, Development 124:2191-2201 were injected with gfp dsRNA. Injected males were affected by unc-22 and gfp dsRNA to the same extent as injected hermaphrodites. No RNAI interference was detected in F1 progeny or injected males (40 to 200 F1 animals scored for each RNA tested. Therefore, the initial transmission of RNAi to F1 progeny may involve a mechanism active only in hermaphrodites while subsequent transmission to the F2 progeny appears to involve a distinct mechanism, active in both hermanhrodites and males. The harmanhrodites specific step may indicate the existence of a maternal germline process that amplifies the RNAi agent. These data show that extracts from the maternal germline tissues of C. elegans may be used in conjunction with RDE-1 and RDE-4 activity to create and to then amplify RNAi agents.

In addition, the germline factors that amplify the RNAi agents can be identified by mutations that result in an RNAi deficient mutant phenotype. Such factors can be used as additional components of an *in vitro* system for the efficient amplification of RNAi agents.

### Example 8: Sufficiency of Wild-Type Activities of rde-1, rde-2, mut-7, and rde-4 in Injected Animals for Interference Among F1 Self Progeny

To investigate whether the activities of rise-1, rise-2, rise-4, and rus-7, respectively, are sufficient in injected hormaphrodites for interference in the F1 and F2 generations, routes were designed much that wild-type activities of these genes would be present in the injected animal but absent in the F1 or F2 generations. To examine inheritance in the F1 generation (memphotolis) mobiles between Section 1.

(P0) were injected, allowed to produce self-progeny (F1) and the homorygous mutant progeny in the F1 generation were examined for genetic interference (Fig. 8A). To do this, the heterogypus hermaphrolites from each genotype class, rade, ..., nor-G1+; rade-2, unc-13+; rade-1, nor-G1+; rade-2, unc-13+; rade-1, nor-G1+; rade-1, no

In this experiment, the expression of rde-I(+) and rde-4(+) in the injected animal was sufficient for interference in later generations.

These data suggest that treatment of a dsRNA with functional rde-1 and rde-4
20 gene products can produce an agent that activates the remainder of the RNAi pathway.

2 and mut-7 mutant F1 progeny remained resistant.

## Example 9: Requirements for rde-1. rde-2, rde-4, and mut-7 in F1 and F2 interference To examine the genetic requirements for RNAi genes in the F2 generation. F1

male progenty were generated that earry the interference effect as well as one mutant copy of cach respective locus; rds-1, rds-2, and mus-7 (Fig. 9A). Each of these males was then backcrossed with uninjected hermaphrolites homorapyous for each corresponding mutant (Fig. 9A). The resulting cross progeny (F1) included 50% heteroxygotes and 50% homorygote that were distinguished by the presence of the linked marker mutations. The heteroxygotes siblings served an controls and in each case exhibited interference at a forequency similar to that seen in wild-type animals (Fig. 9A). In these crosses, rds-2 and mus-7 homorayous Expressery failed to exhibit interference, indicating that the activities that the activities of the control of t

of these two genes are required for interference in the F2 generation. In contrast, we found that homozygous rela-IT2 animals exhibited wild-type levels of F2 interference (Fig 9A). Control rela-I homozygous generated through identical crosses were completely resistant to pos-I-IEMM when challenged de now with distNA in the F2 generation. In these experiments, 35 rela-I homozygous snimulas generated through crosses shown in Fig. 9A were tested by feeding bacteria expressing pos-I distNA, and 21 similar animals were tested by direct injections of pos-J distNA. All animals tested were resistant to pos-I (RNAi). Thus, rela-I activity in the preceding generations was sufficient to allow interference to occur in rela-I mutant F2 animals while the wild-type activities of rela-2 and mus-I were required directly in the F2 animals for interference.

In this experiment, the expression of rds-1(\*) and rds-4(\*) in the injected animal was sufficient for interference in later generations. The wild-type activities of the rds-2 and mus-7 genes were required for interference in all generations assyed. Thus, rds-2 and mus-7 might be required only downstream or might also function along with rds-1 and rds-4.

These data lend additional support to the concept that an appropriately treated dsRNA could be used as an RNAi agent.

15

#### Example 10: Sufficiency of rde-1 Activity to Initiate RNA Interference in Injected Animals That Lack the Wild-Type Activities of rde-2, mus-7, or rde-4

To ask if rde-2 and mm-2 activities function along with or downstream of rde-1, genetic cross experiments were designed in which the activities of these genes were present sequentially (Fig. 9B). For example, rde-1(+)yde-2(-) animals were injected with par-1 ddRNA and then crossed to generate F1 hermaphrodites homozygous for rde-1(-); rde-2(+). In these experiments rde-1(+) activity in the injected animals was sufficient for F1 interference even when the injected animals were homozygous for rde-2 or mu-7 mutations (Fig. 10B). In contrast, rde-1(+) activity in the injected animals was not sufficient when the injected animals were homozygous for rde-2 or mu-7 lines, rde-1 can et independently of rde-2 and mut-7 in the injected animal, but rde-1 and rde-4 mutat function together. These findings are consistent with the model that rde-1 and rde-4 function in the formation of the inherited interfering agent (i.e., an RNA) agent) while rde-2 and mut-7 fluction at later step necessary for interference.

In summary, the above Examples provide genetic evidence for the formation and transmission of extragenic interfering agents in the C elegents germline. Two C. elegents genes, rde-1, and rde-4, appear to be necessary for the formation of these extragencia agents but not for interference mediated by them. In contrast, the activities of two other genes, rde-2 and mark-7, are required only downstream for interference.

These examples provide evidence that the rde-1 and rde-4 gene products or their homologs (e.g., from a mammal) can be used to prepare agents effective in activating the RNAi pathway.

#### 10 Example 11: rde-4 Sequences

An rde-4 gene was cloned using methods similar to those described in Example 6.

The nucleic acid sequence (SEQ ID NO:4) and predicted amino acid sequence (SEQ ID NO:5) are illustrated in Fig. 10.

Analysis of the rde-4 nucleic acid sequence shows that it encodes a protein (RDE-15 4) with similarities to dsRNA binding proteins. Examples of the homology to X1RBPA (SEQ ID NO:6; Swissprot: locus TRBP XENLA, accession O91836; Eckmann and Jantsch, 1997, J. Cell Biol. 138:239-253) and HSPKR (SEO ID NO:7; AAF13156.1; Xu and Williams, 1998, J. Interferon Cytokine Res. 18:609-616), and a consensus sequence (SEQ ID NO:8) are shown in Fig. 11. Three regions have been identified within the 20 predicted RDE-4 protein corresponding to conserved regions found in all members of this dsRNA binding domain family. These regions appear to be important for proper folding of the dsRNA binding domain. Conserved amino acid residues, important for interactions with the backbone of the dsRNA helix, are found in all members of the protein family including RDE-4 (see consensus residues in Figure 11). This motif is 25 thought to provide for general non-sequence-specific interactions with dsRNA. The RDE-4 protein contains conserved protein folds that are thought to be important for the assembly of the dsRNA binding domain in this family of proteins. Conserved amino acid residues in RDE-4 are identical to those that form contacts with the dsRNA in the crystal structure of the X1RBP dsRNA complex. These findings strongly suggest that RDE-4 is likely to have dsRNA binding activity.

Because RDE-4 contains a motif that is likely to bind in a general fashion to any

daRNA and because RDE-4 appears to function suptream in the generation of RNA is agents, the RDE-4 protein or fragments thereof can be used to convert any daRNA into an RNA is agent. In addition to the daRNA binding domain, RDE-4 contains other functional domains that may mediate the formation of RNA is agents. These domains may 5 provide for interaction between DRE-4 and RDE-1 or for binding to enzymen such as mucleases that convert the daRNA into the RNA ingent. Because of its RNA binding function in RNA interference, the RDE-4 protein and fragments thereof can be used to prepare daRNA that is useful in preparing an RNA ingent.

#### 10 Example 12: Identification of Regions of RDE-1 and RDE-4 that are Required for Creating an RNAi Agent

In vivo and in vitro assays are used to identify regions in RDE-1 and RDE-4 that are important for the generation of RNAi agents. In the in vivo assay, rde-1 and rde-4 are 15 introduced into the corresponding C. elegans mutant strains via transgenes (Tabara et al., Cell 99:123 (1999); and Example 13). Important functional domains in RDE-1 and RDE-4 are defined by systematically altering the proteins followed by reintroduction into mutant animals to test for rescue of the RNAi deficient phenotype. A series of nested deletions are analyzed for rescue activity for both rde-1 and rde-4. Specific point 20 mutations are used to analyze the importance of specific amino acids. Chimera's are produced between RDE proteins and related proteins and genes. For example, coding sequences from RDE-1 homologs from the worm or from human are tested for their ability to rescue rde-1 mutants. Replacing the RDE-4 dsRNA binding motif with a distinct RNA binding motif, e.g., one that recognizes a specific viral dsRNA sequence or 25 a ssRNA sequence will alter the specificity of the RNAi response perhaps causing sequence-specific or ssRNA-induced gene targeting. In one form of the in vitro assay, whole protein extracts from rde-1 or rde-4 deficient worm strains are used.

Recombinant RDE-1 or RDE-4 is then added back to reconstitute the extract. Altered RDE-1 and RDE-4 proteins (described above, including deletions, point mutants and chimensa) are made in vitro and then tested for their ability to function when added back to these extracts. RNAi activity is analyzed by injecting the reconstituted extracts directly into animals or by assaying for the destruction of an added in vitro synthesized

target mRNA.

#### Example 13: Rescue of rde-4 Animals

and other RNAi pathway components.

Rescue of azimala (e.g., C. elegans) that are mutant for an RNAi pathway is a 
susful method for identifying sequences from RNAi pathway genes that encode 
functional polypeptides, e.g., polypeptides that can eliminate the mutant phenotype. 
An example of such a method for identifying ride-f mutant animals is as follows. 
PCR using primers located 1 kb upstream and 500 nucleotides downstream of the open 
reading frame (T20G5.11; illustrated in Fig. 12) are used to amplify the ride-4 gene from 
10 C. elegans genomic DNA. The resulting PCR product is then injected along with reporter 
constructs described in Tabans et al. (Cell 99:123 (1999); incorporated herein in its 
entire by verference), and the property of the injected animal are assayed for rescue of 
the RNAi deficient phenotype. The PCR product can also be cloned into a plasmid 
verter for sits directed mutational analysis of RDE-4 (see Example 12). Co-digication of 
15 such a wild they RDE-4 plasmid and altered derivates can be used to identify functional 
15

#### Other Embodiments

domains of rde-4. Similar methods can be used to identify functional domains of rde-1

TOUR

20 It is to be understood that while the invention has been described in conjunction with the detailed description thereof, the foregoing description is intended to illustrate and not limit the scope of the invention, which is defined by the scope of the appended claims. Other aspects, advantages, and modifications are within the scope of the following claims.

25

#### What is claimed is:

- 1. An isolated nucleic acid molecule comprising a nucleotide sequence encoding
   2 an RDE-I polypoptide, wherein the nucleic acid molecule hybridizes under high
- 3 stringency conditions to the nucleic acid sequence of Genbank Accession No. AF180730
- (SEQ ID NO.2) or its complement, or nucleic acid sequence set forth in SEQ ID NO.1 or
- 5 its complement.
  - The isolated nucleic acid of claim 1, wherein the nucleic acid can complement an rde-1 mutation.
- An isolated nucleic acid of claim 1, wherein the nucleotide sequence encodes
   the amino acid sequence of SEO ID NO:3.
- 4. A substantially pure RDE-1 polypeptide encoded by the isolated nucleic acid
   of claim 1.
  - An antibody that specifically binds to an RDE-1 polypertide.
- 6. A method of enhancing the expression of a transgene in a cell, the method
   comprising decreasing activity of the RNAi pathway.
  - 7. The method of claim 6, wherein rde-2 expression or activity is decreased.
- An isolated nucleic acid molecule comprising a nucleotide sequence encoding
- an RDE-4 polypeptide, wherein the nucleic acid molecule hybridizes under high stringency conditions to the nucleic acid sequence of SEQ ID NO:4 or its complement.
- 9. The isolated nucleic acid of claim 8, wherein the nucleic acid can complement
   an rde-4 mutation.
- An isolated nucleic acid of claim 8, wherein the nucleotide sequence encodes
   the amino acid sequence of SEQ ID NO:5.
- 11. A substantially pure RDE-4 polypeptide encoded by the isolated nucleic acid
   of claim 8.
  - 12. An antibody that specifically binds to an RDE-4 polypeptide.
- 13. A method of preparing an RNAi agent, the method comprising incubating a
   dsRNA in the presence of an RDE-1 protein and an RDE-4 protein.

14. A method of inhibiting the activity of a gene, the method comprising
 introducing an RNAi agent into a cell, wherein the dsRNA component of the RNAi agent
 is targeted to the gene.

15. The method of claim 14, wherein the cell contains exogenous RNAi

sequences.

16. The method of claim 14, wherein the exogenous RNAi sequence is an RDE-1 polypeptide or an RDE-4 polypeptide.

#### INTERNATIONAL SEARCH REPORT

International application No. PCT/US00/28470

A.	CL		SUBJECT	

IPC(7) :C07H 21/04; C07K 14/435, 16/18; C12N 15/63, 15/67 US CL : 536/23.1; 530/350, 387.1; 435/440 According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 536/23.1: 530/350. 387.1: 435/440

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used) STN/CAS (Medline, Embase, Biosis, Caples); US patest database

search terms: row interference; dsRNA; RNA; RNA interference mechanism; genetic interference; gote silencing; genetic basis

c. poc	UMENTS CONSIDERED TO BE RELEVANT	
Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.

#### INTERNATIONAL SEARCH REPORT

International application No. PCT/IS00/28470

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING This ISA found multiple inventions as follows:

This application contains the following inventions or groups of inventions which are not so linked as to form a single inventive concept under PCT Rule 13.1. In order for all inventions to be searched, the appropriate additional search fees must be paid.

Group 1, claim(s)1-4, 8-11 and 13, drawn to an isolated studies acid molecule and a method of using it Group II, claim(s) 5, drawn to an antibody that specifically binds RDE-1 polypeptide.

Group III, claim(s) 6 and 7, drawn to a method of enhancing the expression of a transgene in a cell. Group IV, claim(s)12, drawn to an antihody that specifically binds RDE-4 polypeptide.

Group V, claim(s) 14-16, drawn to a method of inhibiting the activity of a gene.

The inventions listed as Groups I-V do not relate to a single inventive concept under PCT Rule 13.1 because, under PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons: Group I is drawn to an idolated nucleic acid molecule which has the special technical feature of encoding an RDE-I polypeptide Group II is drawn to an antibody which has the special technical feature of binding specifically to RDE-1 polypeptide. Group III is drawn to a method of enhancing expression of a transgene in a cell which has the special technical feature of decreasing the activity of the RNAi pathway. Group IV is drawn to an autibody which has the special technical feature of binding specifically to RDE-4 potypeptide. Group V is drawn to a method of inhibiting the activity of a gene which has the special technical feature of introducing an RNAi agent into a cell.
